

The basics

TB and HIV

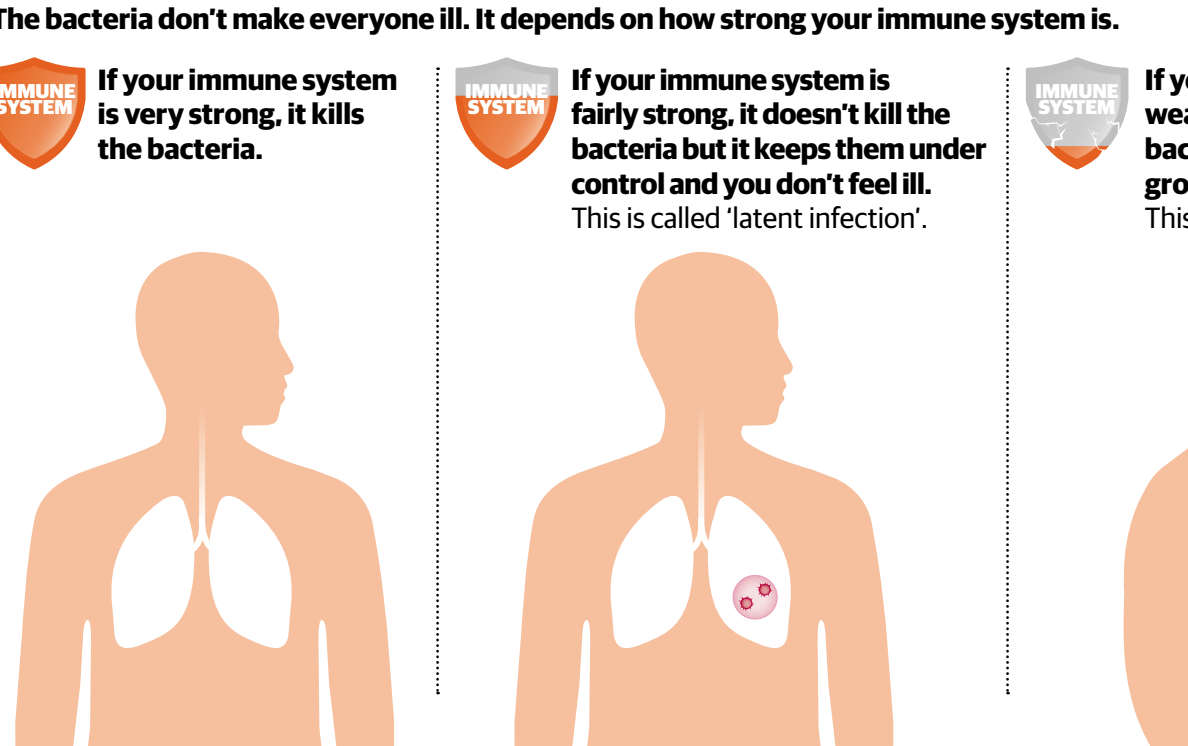

If HIV has weakened your immune system, you are more vulnerable to tuberculosis (TB).

1 TB is an infection caused by bacteria.

2 The bacteria pass from one person to another through the air. They can enter your body when you breathe.

3 The bacteria usually infect the lungs, but they can also infect other parts of the body (such as bones and joints).

4

The bacteria don't make everyone ill. It depends on how strong your immune system is.

If your immune system is very strong, it kills the bacteria.

If your immune system is fairly strong, it doesn't kill the bacteria but it keeps them under control and you don't feel ill. This is called 'latent infection'.

If your immune system is weak, it can't control the bacteria. The TB bacteria grow and make you ill. This is called 'active infection'.

If your immune system is weak, it can't control the bacteria. The TB bacteria grow and make you ill. This is called 'active infection'.

Symptoms of TB

A cough that lasts for more than three weeks

Loss of appetite

Fever

Tiredness

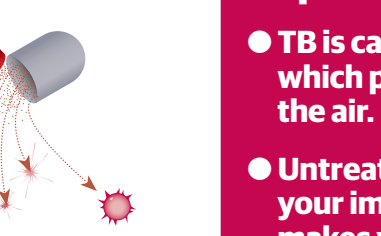

Night sweats

Weight loss

5 You can kill the bacteria with TB drugs.

6 You can make your immune system stronger with anti-HIV drugs.

Important points

- TB is caused by bacteria which pass through the air.
- Untreated HIV weakens your immune system. It makes you more likely to become ill from TB than other people.
- TB is a very serious illness but there is a cure.

Notes

In people with HIV, the most common cause of a **weakened immune system** is not taking anti-HIV drugs. The immune system can sometimes also be weakened by other medical conditions, not having enough to eat, poor housing, pregnancy, old age or being very young.

Want to find out more?

- For more information on this topic**
- Read our 'How TB is passed on' leaflet.
 - Read our 'Treatment for TB and HIV' leaflet.
- For more information about HIV**
- Visit our website www.aidsmap.com.
- Speak to an adviser at THT Direct (phone: 0808 802 1221).
